## ADDITION OF SULFUR DIOXIDE <br> using a solution of sulfur dooxid in water

Some winemakers choose to use solutions of sulfur dioxide in water for additions. The solutions are created by bubbling gaseous $\mathrm{SO}_{2}$ into a measured volume of chilled water or by the direct addition of liquid $\mathrm{SO}_{2}$, creating a saturated solution of $\mathrm{SO}_{2}-\mathrm{H}_{2} \mathrm{O}$. This is not the same as creating a solution by dissolving potassium metabisulfite in water. At $20^{\circ} \mathrm{C}\left(68^{\circ} \mathrm{F}\right)$ the solubility of SO 2 in water is $11.28 \%$ by weight.
(a) Prepare a solution of $\mathrm{SO}_{2}-\mathrm{H}_{2} \mathrm{O}$ in a well-ventilated area using appropriate safety measures. In cold water, solutions of 6-8\% are readily produced.
(b) Using the data in the following table ${ }^{1}$ you can plot concentration of $\mathrm{SO}_{2} \mathrm{vs}$. specific gravity at various temperatures. Please note that this chart is not accurate for aqueous solutions of potassium metabisulfite because of the density contribution of the cations.

| $\mathrm{SO}_{2}$ Concentration <br> $(\% \mathrm{wt} / \mathrm{vol})$ | Specific Gravity at |  |  |
| :---: | :---: | :---: | :---: |
| 1.0 | 1.004 | $20^{\circ} \mathrm{C}\left(69^{\circ} \mathrm{F}\right)$ | 1.003 |
| 2.0 | 1.009 | 1.008 | 1.000 |
| 3.0 | 1.014 | 1.013 | 1.005 |
| 4.0 | 1.020 | 1.018 | 1.010 |
| 5.0 | 1.025 | 1.023 | 1.014 |
| 6.0 | 1.030 | 1.028 | 1.019 |
| 7.0 | 1.035 | 1.032 | 1.024 |
| 8.0 | 1.040 | 1.037 | 1.028 |
|  |  | --- |  |

(c) Using the chart or plot from (b) above and a specific gravity hydrometer, determine the SO2 concentration of the solution. For example, a reading of 1.028 at $20^{\circ} \mathrm{C}$ corresponds to a concentration of $6.0 \%$ ( $60 \mathrm{~g} / \mathrm{L}$ or $60,000 \mathrm{mg} / \mathrm{L}$ ).
(d) Additions can then be calculated using the following formula:
$\frac{\text { desired addition in } \mathrm{ppm} \times \text { volume in gallons } \times 3.785 \mathrm{~L} / \mathrm{gal}}{\mathrm{SO}_{2} \text { solution concentration in } \mathrm{g} / \mathrm{L}}=\underset{\text { milliliters }}{\text { addition in }}$
For example, the volume of $6 \%$ solution needed for a $10 \mathrm{ppm}(\mathrm{mg} / \mathrm{L}$ ) addition to $1,000 \mathrm{gallons}$ (or 37.85 hL ) of wine is 630 mL .
